

REVISION OF *PLATHYMEНИA* (*LEGUMINOSAE-MIMOSOIDEAE*)

M. C. WARWICK* & G. P. LEWIS†

Plathymenia (*Leguminosae-Mimosoideae*) has been variously regarded as comprising one to three species and one variety. The genus is here considered to be monospecific, containing only *Plathymenia reticulata*. This is in agreement with the conclusion of Ducke in 1925. A full description is given of *P. reticulata* in its emended sense, with notes on ecology, uses, vernacular names and a list of herbarium specimens examined.

Keywords. Cerrado, *Fabaceae*, lectotypification, monospecific, neotropics, seasonally dry tropical forest, vinhático.

INTRODUCTION

Plathymenia Benth. (*Leguminosae-Mimosoideae*) is a genus of tropical trees native to South America, found primarily in the Brazilian cerrado, but also in Bolivia, northern Paraguay and Surinam. It was first described by Bentham (1842) who recognized two species: *P. reticulata* Benth. and *P. foliolosa* Benth. Burkart (1939) included three species in the genus, adding *Plathymenia modesta* (Speg.) Burkart, based on *Pirothantha modesta* Speg. which had been described in 1916. In addition, Chodat & Hassler (1904) recognized var. *paraguariensis* Chodat & Hassler under *P. foliolosa* Benth. Ducke (1925), on the other hand, reduced the genus to one species, *P. reticulata*. Lewis (1987) also cast doubt on the distinctness of some of these species and a revision is now appropriate, especially because the Brazilian Institute of Agricultural Research (EMBRAPA) recently classified *P. reticulata* as one of the most useful species in the Brazilian cerrado (Almeida *et al.*, 1998). The main characters used to distinguish it from *P. foliolosa* by Bentham (1842, 1876) and Heringer (1956) were size, habitat, inflorescence indumentum and the numbers of pinnae per leaf and leaflets per pinna. There is, however, no correlation between morphology and geography, and there are no recognizable ecotypes. There is a continuum in size up to 12m and there are no characters to separate the trees in one habitat from those in another. The numbers of pairs of pinnae and leaflets vary continuously; similarly the degree of pubescence on all parts of the plant ranges from almost glabrous to densely hairy. The ovary is always densely hairy, and when the petals open the ovary can give the inflorescence the appearance of being hairy, but examination of the other parts of the flower reveals continuous variation, with flowers very occasionally completely glabrous or densely hairy.

* Royal Botanic Garden Edinburgh, 20A Inverleith Row, Edinburgh EH3 5LR, UK.

† Royal Botanic Gardens, Kew, Richmond, Surrey TW9 3AB, UK.

Based on the above observations we consider the genus to be monospecific, a view that has also been expressed by Ducke (1925). Two recent molecular systematic papers by Lacerda *et al.* (2001, 2002) have focused on the genus *Plathymenia*. Their 2002 paper is relevant to our study because the authors recognize two species, *P. reticulata* and *P. foliolosa*. However, they demonstrated that one population of *P. foliolosa*, located in a region where both occur, presented several RAPD markers that were characteristic of *P. reticulata*, suggesting the occurrence of gene flow between the two species. This adds support to our conclusion that *Plathymenia* is monospecific. Lacerda *et al.* (2002) analysed populations only within the state of Minas Gerais. If they had sampled more widely across the whole range of the genus, we predict that gene flow would have been encountered between other populations across the full geographical range of this species.

Bentham (1842) described the genus *Plathymenia* based on specimens he had mentioned earlier (Bentham, 1840). The specimens collected by Gardner in Ceará he named *Plathymenia foliolosa*; those from Minas Geraes (*sic*), which he named *P. reticulata*, were collected by Claussen, Langsdorff and Pohl. *Claussen & Delessert* 110 is the only specimen collected in Minas Gerais in 1839 that Bentham could have seen before his reference to *Plathymenia* in 1840 and is here designated the lectotype of *P. reticulata*.

The anthers examined under the scanning electron microscope were prepared using techniques described in Warwick & Helfer (1990).

TAXONOMY

***Plathymenia* Benth., Hook. Journ. Bot. 4: 333 (1842).**

Type: *Plathymenia reticulata* Benth.

Deciduous trees. Leaves bipinnate. Inflorescence an axillary raceme. Flowers pedicellate. Bracts caducous. Calyx 5-lobed, valvate in bud; teeth unequal. Corolla with 5 free petals. Androecium of 10 free stamens; anthers dorsifixed. Gynoecium shorter than androecium; ovary stipitate, with 10–12 ovules. Fruit flattened, dehiscent along both sutures, 10–12-seeded.

***Plathymenia reticulata* Benth., Hook. Journ. Bot. 4: 334 (1842). Fig. 1.**

Type: Brazil, Minas Gerais, *Claussen & Delessert* 110 (lecto. K!, chosen here).

Syn.: *Plathymenia foliolosa* Benth., Hook. Journ. Bot. 4: 334 (1842). Type: Brazil, Ceará, *Gardner* 1589 (holo. K!, iso. K!).

Plathymenia foliolosa var. *paraguariensis* Chodat & Hassler, Plantae Hasslerianae 2: 561 (1904). Type: Paraguay, near Concepción, x 1901/02, *Hassler* 7674 (iso. K!).

Plathymenia modesta (Speg.) Burkart, Darwiniana 3(3): 466 (1939).

Pirottantha modesta Speg., Anal. Soc. Ci. Arg. 82: 226 (1916).

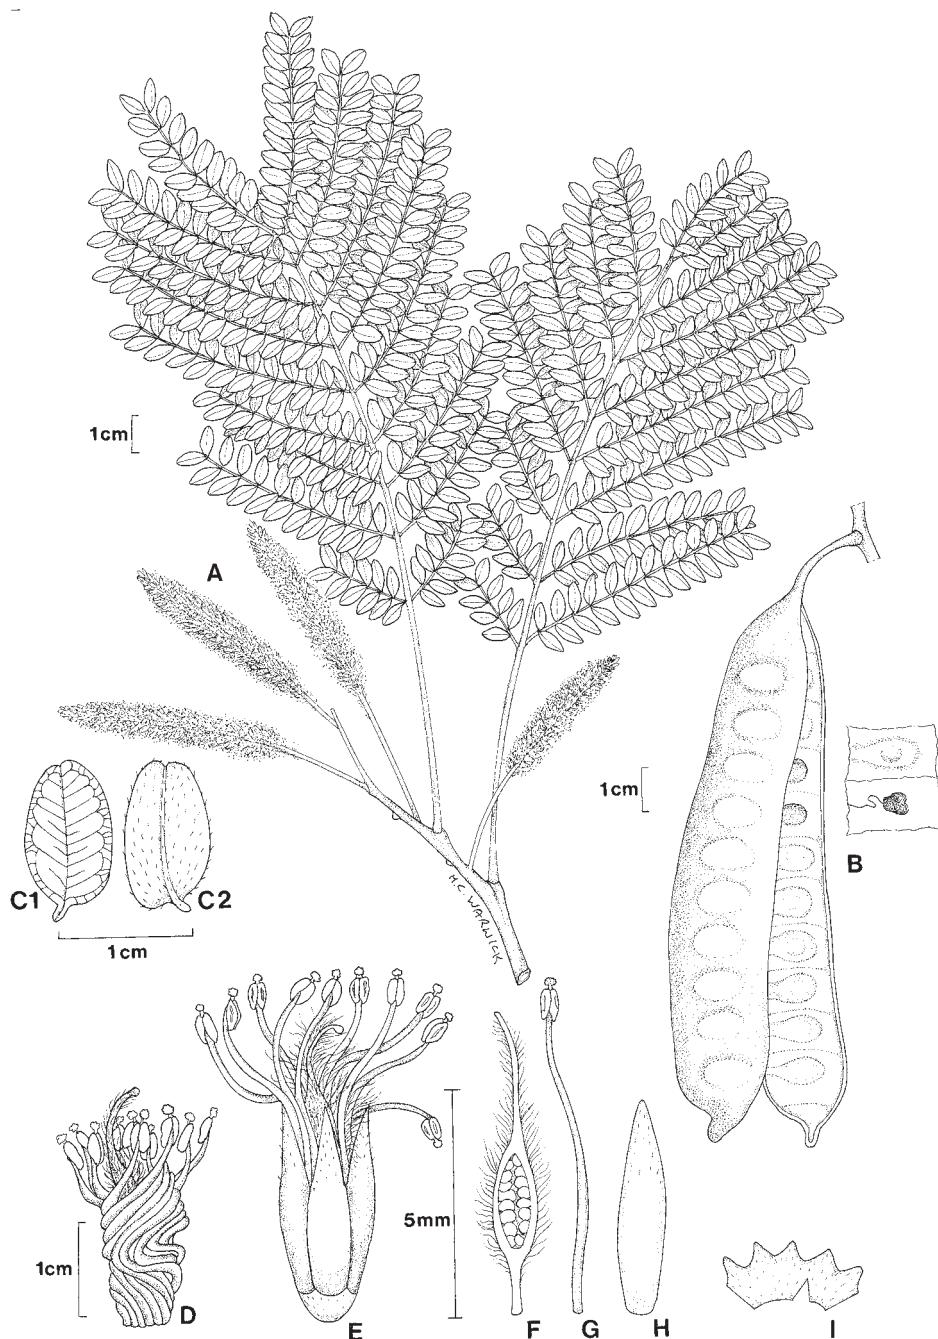

FIG. 1. *Plathymenia reticulata*: A, habit (Ratter et al. R2538); B, pod and enlargement of seeds in separate membranous covers (Nee & Coimbra 35848); C1, leaflet upper surface; C2, leaflet lower surface; D, stamens before corolla opens; E, mature flower; F, gynoecium; G, stamen; H, petal; I, calyx. E, F, G, H & I all at same scale. Drawn by Maureen Chisam Warwick.

Slender, straight *tree* to 12(–40)m; dbh 3–30(–90)cm; branching open; crown spreading in forest, gnarled or tortuously branched in open cerrado. *Bark* grey to pale grey, thick, fissured, rough and corky, characteristically exfoliating in irregular plates; wood cream to light straw-coloured, surrounded by red bark, cortex mauve-pink; inner bark pinkish light brown; exudate transparent. *Twigs* grey or dark brown and corky when old; younger twigs ridged, shiny, almost black, lenticellate, glabrous to sparsely hairy with short erect hairs or with long pale hairs evenly distributed, becoming sparsely hairy or glabrous when mature. *Leaves* bipinnate, 8–28cm long, *petiole* 1.6–8.5cm long, glabrous to sparsely hairy, rarely densely hairy; rhachis with long, sparse hairs predominantly on upper surface, occasionally densely hairy or glabrous; *pinnae* 3–12 pairs per leaf, paripinnate, alternate or opposite; *petiolule* 2–10mm long, sparsely to densely hairy; pinna rhachis usually more densely hairy than leaf rhachis, rarely glabrous; *leaflets* 6–20 pairs per pinna, alternate or opposite, 4–17 × (0.8–)2–10.5mm, linear to elliptic; apex retuse, sometimes with a small mucro, rarely rounded; base asymmetric; petiolule densely hairy, rarely glabrous; leaflet lamina glabrous above, occasionally with sparse evenly distributed hairs, glabrous below but with a few long hairs predominantly on mid-vein or near base, or densely hairy; margins with few hairs; venation distinct on upper surface, rarely indistinct, mid-vein flush with lamina surface, raised below; secondary veins 6–10 pairs, at 70–90° to mid-vein and merging with next vein above before reaching margin; tertiary veins reticulate, frequently indistinct. *Inflorescence* 6.5–11cm long, axillary, racemose, erect; pedicel persistent, 0.5–2mm long, glabrous; bracts triangular, with long hairs especially on margin, caducous. *Flowers* 5–10mm long, variously described as dull white, green-white, cream, creamish yellow, creamish pale green, light green and very pale yellow-green, sweetly scented, similar to *Citrus* blossom (G.P. Lewis *et al.* 878) or *Philadelphus coronarius* (R.M. Harley *et al.* 10379); *calyx* 2–4mm long, with triangular lobes 0.5–2mm long, with long hairs predominantly on tube, rarely densely hairy, very pale yellow-green; *petals* 5, free, 3–4.5 × 0.9–1.2mm, usually with a few long apical hairs, rarely completely glabrous or densely hairy throughout their length; stamens 10, 6–8mm long, glabrous, packed tightly around ovary before corolla opens; filaments 5–7mm long, white; anthers 0.5–0.7mm, cream or yellow with a large apical stalked gland (Fig. 2); style 2.5–4mm long, with long pale hairs extending from ovary to within 1mm of stigma; stipe 1–2.5mm, usually with hairs extending down from ovary; ovary 1.8–2.5 × 0.6–1mm, densely hairy, ovules 10–18. *Fruit* a flattened, pendent, stipitate, slightly curved pod, 7.8–16 × 1.4–3.6cm, glabrous, the thin, membranous endocarp separating from the pericarp and splitting between the seeds to enclose each in a subquadrate to rectangular papery envelope; immature pods green, becoming chestnut brown at maturity; seeds laterally compressed, 6–14 per pod, ovate to almost circular, 6–14 × 4–8mm.

Derivation. Greek, *platy*=flat, *hymen*=membrane, referring to the membrane within which the seed is enveloped (see Heringer, 1956, p. 3).

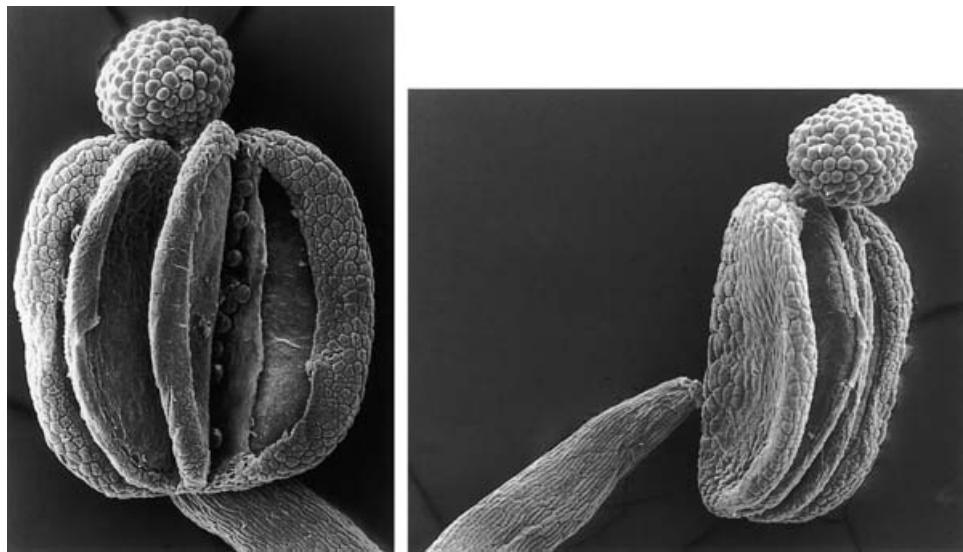

FIG. 2. Scanning electron micrographs of anther of *Plathymenia reticulata* showing apical gland (Fiebrig 4012), $\times 330$. Photographs by Maureen Chisam Warwick.

Distribution. BRAZIL. Amapá, Bahia, Brasília, Ceará, Distrito Federal, Espírito Santo, Goiás, Maranhão, Mato Grosso, Mato Grosso do Sul, Minas Gerais, Pará, São Paulo and Transamazônia. SURINAM. Sipaliwini. BOLIVIA. Andrés Ibáñez, Santa Cruz. PARAGUAY. Río Apa and Río Aquidaban. Fig. 3.

Altitude. Mainly 300–1075m, one specimen from 30m (H.N. Whitford & F. Silveira 74).

Flowering. September–December; Pott & Pott (1997) report pods maturing almost one year later.

Habitat and ecology. *Plathymenia reticulata* grows predominantly in Brazilian cerrado vegetation and seasonally dry tropical forest, as defined by Pennington *et al.* (2000); a few specimens occur on rocky ridges (J.A. Ratter *et al.* R813, H.S. Irwin *et al.* 27461) or summits (R.M. Harley *et al.* 21235). The tallest specimens collected are from cocoa (*Theobroma*) plantations and remnants of Atlantic forest where better soils and higher rainfall probably account for their size.

Vernacular names. **Brazil** (all states): vinhático, vinhático-branco, vinhático-castanho, vinhático-rajado, vinhático-testa-de-boi, pau-amargo, pau de candeia, oiteira. **Espírito Santo:** vinhático amarela. **Maranhão:** pati, pupunha rana, candeia (firewood). **Minas Gerais:** vinhático do campo, amarelinho. **Pará:** candrea. **Bahia:** vinhático flor de algodão, vinhático testa de burro. **Bolivia, Santa Cruz:** harca, jarca.

Uses. An important timber tree producing high quality wood. Pott & Pott (1997) report that smaller trees are used for fence posts which last 50 years and are very

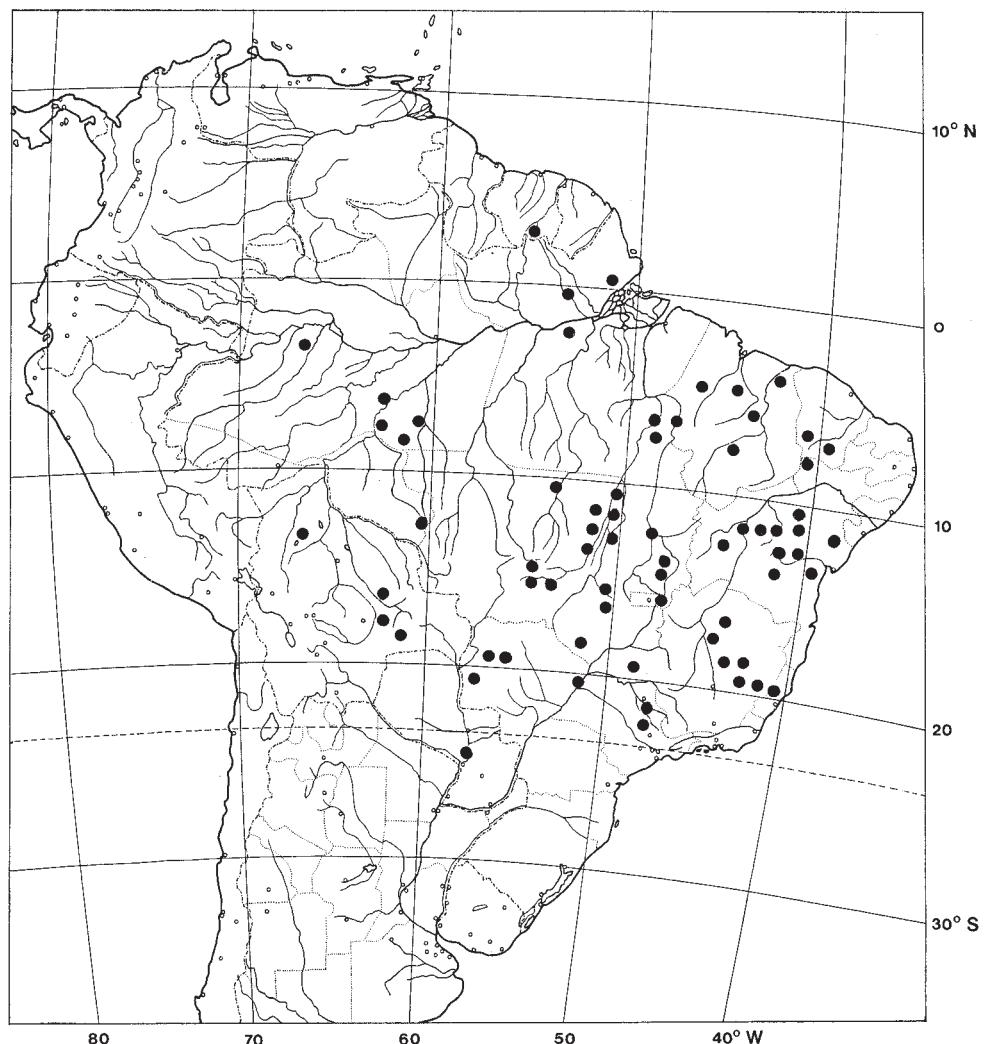

FIG. 3. Map of South America showing distribution of *Plathymenia reticulata*; each dot represents one collection.

resistant to termites; larger trees are used for furniture, floors and in ship building. *Plathymenia reticulata* might be useful in the recovery of degraded areas as it regenerates after being cut and grows well under drought conditions (Pott & Pott, 1997). Ratter *et al.* R1497, R1715 report the wood to be very inflammable but apparently it tolerates light fire (Pott & Pott, 1997). The bark is also used to make a medicinal bath for various ailments (Pott & Pott, 1997). EMBRAPA has classified *P. reticulata* as one of the most important and useful plant species of the Brazilian cerrado, an area rich in biodiversity but endangered by agricultural development (Almeida *et al.*, 1998).
